Creating and using graphs in Python Graphs have been used since the ancient times as a tool for analysis and visualisation. In this post, we will look at the different types of graphs, please refer to this post. However, it is also important to understand how we can use Python to create and use these graphs, and this post looks at this. Graphs to describe business processes. Some are only descriptive, some are a mixture of descriptive and visual. We will look at three types. Histograms Histograms are the most basic graphs that can be used to analyse data. These can show the frequency of different values in a data set. You can see an example of a histogram in this histogram showing the distribution of the number of emails sent and received by each employee in a company. Dendrograms Dendrograms can show how relationships between data points change over time, or how the data changes. You can think of dendrograms as 'tree maps' that show how the data changes over time. In the example below, each square represents a day and the number inside is the number of emails sent. We can see the graph is a tree map, with each square representing a day. The first day is connected with the second. The second day with the third, and so on. Cyclic graphs A cyclic graph is a graph that has the same data for each node. Each node has edges to previous nodes but not to other nodes. A cyclic graph showing how the number of different character and we can see that every time we look at a new character, it is connected to the character that came before it.
